Abstract: Medical tourism has developed rapidly worldwide, especially in Asia, and one of the most important problems facing the patient-tourists is the selection of the optimum destination. In this paper, we present a novel multiple criteria group decision making (MCGDM) methodology to evaluate and rank the medical tourism destinations vague based on vague information. A systematic assessment and selection model was constructed by investigating MCGDM problems with neutrosophic fuzzy preference relations (NFPRs). We began by defining NFPRs which allow the patient-tourists lacking information, time or patience, to express their uncertainty and hesitancy about the given preference values. The additive consistency and acceptable consistency for NFPRs were then proposed. Furthermore, the approach to improve the consistency for NFPRs was also validated and a series of aggregation operators were developed. In addition, we presented a systematic MCGDM method using NFPRs (MCGDM-NFPRs) in this paper to rank the medical tourism destinations. Then our proposed approach was applied to two cases considering different kinds of original data to prioritize medical tourism places. Finally, the applicability and feasibility of proposed approach were verified by the comparison with other previous methods, along with some analyses and a comprehensive discussion.

Key words: Neutrosophic fuzzy preference relations; Consistency; Aggregation operators; Multiple criteria group decision making; Medical tourism.

1. Introduction

Medical tourism is a global industry that focuses on obtaining medical treatments in foreign destinations. Factors that have contributed to the rapid development of medical tourism include expensive health-care in home country, long waiting lists for certain procedures, the increase in the affordability of overseas traveling, the melioration of technology for health treatments in many states and profitable change rates in destination countries, among others [1]. Traditionally, people preferred to travel from the underdeveloped countries to the more developed ones to avail the advanced medical treatments that were lacking in their homeland [2,3]. But in recent times, this trend has reversed with more people from the developed countries travelling to some third-world countries. Several reasons have contributed to this phenomenon such as affordable healthcare, easy availability of skilled manpower, rapid development of medical facilities in recent years, fewer restrictions on policies and laws and so on.

The most popular international healthcare destinations that have also attracted the attentions of many researchers include South Africa [4], Thailand [5,6], Mongolia [7], Hong Kong [8], Barbado [9], India [10], and South Korea [11]. Medical tourism industry of India especially, which is researched in this paper, is a rapidly growing sector in the tourism industry and is estimated to have been worth \$3 billion in 2015. Furthermore, it is projected to reach \$7-8 billion by 2020 [12].

Although many studies have been conducted on the social impact of medical tourism [7-9,11,13], there are not many tools available for patients to evaluate the various medical tourism destinations and select the most suitable ones for their needs. Roy et al. [14] argued that this issue could be solved by

considering of the interests of certain stakeholders like medical infrastructure, logistics enterprises and government regulations, in assessing the weight of a multiple criteria set. Eissler et al. [15] provided an increased understanding of the experience in selecting health care internationally, from the perspective of patients. Taken together, the evaluation and selection of medical sites could be regarded as a multiple criteria decision making (MCDM) problem.

However, due to the great complexity of the real world, it is difficult to obtain enough information about each destination (alternative) under different criteria. Therefore, it is worth considering a pairwise comparison of a set of available alternatives. In these cases, the preference relations (PRs) [16], which are a useful tool in modeling decision processes, are always efficiently used to describe experts opinions. In recent years, PRs have attracted a lot of attentions and undergone developments as the most common representative structures of information in the field of GDM. Due to the uncertainty of decision related problems, it is difficult for a decision maker (DM) to offer a crisp preference degree of pairwise judgments. In order to overcome such issues, the fuzzy preference relations (FPRs) [17,18] and some extensions [19,20] have been proposed.

As one of the most useful extensions of FPRs, the intuitionistic preference relation (IPR) [21] and its extensions have generated a lot of interests [22-25], which allow DMs express their affirmation, negation and hesitation. For example, Chiclana et al. [26] gave the method to tackle a situation with unknown values in reciprocal IPRs by using asymmetric FPR. Based on the above method, Ureña et al. [27] proposed a confidence-consistency driven GDM method for incomplete reciprocal IPRs, which could overcome the computational complexity. In addition, Xu [28] developed a consensus reaching method in GDM according to the compatibility measures. Wang et al. [29] presented an acceptable consistency-based procedure for GDM with IPRs and Wu [30] put forward a multiple

criteria group decision making (MCGDM) framework with the consistency of IPRs based on the exponential score function. Zeng et al. [31] constructed a novel model for interactive GDM with IPRs. Zhang et al. [32] further investigated the prioritization and aggregation of the IPRs. Furthermore, many extensions of IPRs, such as interval-valued IPRs [33], intuitionistic multiplicative PRs [34], hesitant-IPRs [35], have been proposed and developed.

The consistency of PRs, which has a direct effect on reaching consistent and reasonable conclusions, is a vital factor in designing good decision making models and has therefore been researched extensively [36-39]. Studying consistency is related to the concept of transitivity, such as the max-min transitivity [40,41], the max-max transitivity, the additive transitivity and so on [42,43]. In particular, the additive transitivity, which would be used in this paper, is stronger than restricted max-max and restricted max-min ones and weaker than max-max and max-min ones. Furthermore, many consistency measurements about different kinds of PRs have been studied; Liao et al. [44] introduced multiplicative consistency, perfect multiplicative consistency and acceptable multiplicative consistency for HFPRs, Wang and Xu. [45] developed additive consistency measure and weak consistency measure for the extended hesitant fuzzy linguistic preference relations, and Rallabandi et al. [46] proposed an improved consistency ratio for the pairwise comparison matrix. In addition, the aggregation approaches are important to solve MCGDM problems, which could aggregate several values. Many researches have contributed to the aggregation of FPRs, such as Li et al. [47] came up with the conversion of interval multiplicative weights to acceptable interval multiplicative PRs and established an interval multiplicative weight derivation model, Wang and Lin [48] explored the priority weight elicitation for triangular fuzzy multiplicative PRs, and Wang [49] presented a linear goal programming framework in order to obtain normalized interval weights from interval FPRs.

We can conclude from all these studies that the existing forms of FPRs cannot deal with a situation where experts are hesitant about their judgments due to the lack of information and the complexity of the real environment. It is obvious therefore that consistency is a vital and useful tool to ensure the logic and efficiency of a preference. The aim of this paper is to propose neutrosophic fuzzy preference relations (NFPRs), which permit a DM to give his/her membership or non-membership of the preference about one destination (alternative) over another and the unsure degree about the two values simultaneously, and to give a novel MCGDM method using NFPRs (MCGDM-NFPRs) on the basis of consistency measurements in order to evaluate and prioritize the medical tourism destinations.

The remainder of this paper is organized as follows. Section 2 reviews some basic concepts of neutrosophic set (NS), single valued neutrosophic set (SVNS) and the corresponding operational laws. Section 3 introduces the concept of NFPR, its additive consistency and acceptable consistency according to FPR, IPR and the additive consistency of IPR and some operations of single valued neutrosophic element (SVNE). This is followed by section 4 that describes a method to improve the consistency of NFPRs and proves some properties. The MCGDM-NFPRs model is proposed in section 5 and evaluated further for medical tourism sites selection in section 6 by comparing two cases with two previous methods. The conclusion of this study is finally pointed out in section 7.

2. Preliminaries

In this section we discuss some definitions, operations and properties of SVNS as defined in previous studies [50,51], along with the definition of FPR and its additive consistency which will be used in the rest of the paper.

Definition 2.1 [51] Let X be a space of points (objects) with generic elements in X denoted by x . An SVNS A in X is characterized by truth-membership function $T_A(x)$,

indeterminacy-membership function $I_A(x)$, and falsity-membership function $F_A(x)$ for each point x in X , $T_A(x), I_A(x), F_A(x) \in [0,1]$.

For convenience, an SVN $A = \{x, T_A(x), I_A(x), F_A(x) | x \in X\}$ is denoted by the simplified symbol $A = \langle T_A(x), I_A(x), F_A(x) \rangle$ for any x in X . In this paper, we call $\tilde{a} = \langle T_a(x), I_a(x), F_a(x) \rangle$ an SVNE where $x \in X$.

Definition 2.2 [51] The complement of an SVN $A = \langle T_A(x), I_A(x), F_A(x) \rangle$ is denoted by A^c and $A^c = \langle F_A(x), 1 - I_A(x), T_A(x) \rangle$. The following expressions are defined for the two SVN A and B :

- (1) $A \subseteq B$ if and only if $T_A(x) \leq T_B(x)$, $I_A(x) \leq I_B(x)$, $F_A(x) \leq F_B(x)$ for any x in X ,
- (2) $A = B$ if and only if $A \subseteq B$ and $B \subseteq A$.

Definition 2.3 [51] For two SVN A and B , the operational relations are defined as follows:

- (1) $A \cup B = \langle \max(T_A(x), T_B(x)), \min(I_A(x), I_B(x)), \min(F_A(x), F_B(x)) \rangle$, for any x in X ,
- (2) $A \cap B = \langle \min(T_A(x), T_B(x)), \max(I_A(x), I_B(x)), \max(F_A(x), F_B(x)) \rangle$, for any x in X ,
- (3) $A \times B = \langle T_A(x) + T_B(x) - T_A(x)T_B(x), I_A(x)I_B(x), F_A(x)F_B(x) \rangle$, for any x in X .

3. NFPR and its consistency measurements

This section defines the notion of NFPR based on the definitions of FPR [52] and IPR [53]. The additive consistency and acceptable consistency of NFPR, which are important to ensure the consistent logic of DMs, are proposed based on the additive consistency of IPR [54].

Definition 3.1 [52] An FPR P on a set of alternatives X on the product set $X \times X$ is a fuzzy set, which is characterized by a membership function μ_p where $\mu_p : X \times X \rightarrow [0,1]$.

When the cardinality of X is small, the PR could be represented by a matrix $P = (p_{ij})_{n \times n}$, where p_{ij} satisfies the following characteristics:

$$0 \leq p_{ij} \leq 1, \quad p_{ij} + p_{ji} = 1, \quad p_{ii} = 0.5 \quad \text{for any } i, j \in \{1, 2, \dots, n\}. \quad (1)$$

Definition 3.2 [53] Let $X = \{x_1, x_2, \dots, x_n\}$ be a fixed set, then an IPR \tilde{R} on the set X is represented by a matrix $\tilde{R} = (\tilde{r}_{ij})_{n \times n} \subset X \times X$ where $\tilde{r}_{ij} = \langle (x_i, x_j), \mu(x_i, x_j), \nu(x_i, x_j) \rangle$ for any $i, j \in \{1, 2, \dots, n\}$. For convenience, \tilde{r}_{ij} is denoted by the simplified symbol $\tilde{r}_{ij} = (\mu_{ij}, \nu_{ij})$, composed by μ_{ij} to which x_i is preferred to x_j and ν_{ij} to which x_i is non-preferred to x_j . Furthermore, $\tilde{r}_{ij} = (\mu_{ij}, \nu_{ij})$ satisfies the following conditions:

$$0 \leq \mu_{ij} + \nu_{ij} \leq 1, \quad \mu_{ji} = \nu_{ij}, \quad \nu_{ji} = \mu_{ij}, \quad \mu_{ii} = \nu_{ii} = 0.5 \quad \text{for any } i, j \in \{1, 2, \dots, n\}. \quad (2)$$

Definition 3.3 [54] Let $\tilde{R} = (\tilde{r}_{ij})_{n \times n}$ be an IPR where $\tilde{r}_{ij} = (\mu_{ij}, \nu_{ij})$, \tilde{R} has additive consistency if it satisfies the following conditions:

$$\mu_{ij} + \mu_{jk} + \mu_{ki} = \mu_{kj} + \mu_{ji} + \mu_{ik} \quad \text{for any } i, j \in \{1, 2, \dots, n\}. \quad (3)$$

According to Eqs. (2) and (3), if $\tilde{R} = (\tilde{r}_{ij})_{n \times n}$ is additive consistent, then

$$\nu_{ij} + \nu_{jk} + \nu_{ki} = \nu_{kj} + \nu_{ji} + \nu_{ik} \quad \text{for any } i, j \in \{1, 2, \dots, n\}. \quad (4)$$

Definition 3.4 [55] Given an SVNE $\tilde{a} = \langle T_a(x), I_a(x), F_a(x) \rangle$, then $S(\tilde{a}) = (T_a(x) - F_a(x))(1 - I_a(x))$ is called the score function of \tilde{a} , and $S'(\tilde{a}) = T_a(x) - F_a(x)$ and $H'(\tilde{a}) = T_a(x) + F_a(x)$ are the sub-score function and sub-accuracy functions respectively. These three functions can be used as the basis to compare two SVNEs. By taking a prioritized sequence of score function, sub-score function and sub-accuracy function, an approach is devised for comparing two SVNEs $\tilde{a} = \langle T_a(x), I_a(x), F_a(x) \rangle$ and $\tilde{b} = \langle T_b(x), I_b(x), F_b(x) \rangle$ as follows.

If $S(\tilde{a}) > S(\tilde{b})$, then \tilde{a} is greater than \tilde{b} , denoted by $\tilde{a} > \tilde{b}$;

If $S(\tilde{a}) < S(\tilde{b})$, then \tilde{a} is smaller than \tilde{b} , denoted by $\tilde{a} < \tilde{b}$;

If $S(\tilde{a}) = S(\tilde{b})$, then

If $S'(\tilde{a}) > S'(\tilde{b})$, then \tilde{a} is greater than \tilde{b} , denoted by $\tilde{a} > \tilde{b}$;

If $S'(\tilde{a}) < S'(\tilde{b})$, then \tilde{a} is smaller than \tilde{b} , denoted by $\tilde{a} < \tilde{b}$;

If $S'(\tilde{a}) = S'(\tilde{b})$, then

If $H'(\tilde{a}) > H'(\tilde{b})$, then \tilde{a} is greater than \tilde{b} , denoted by $\tilde{a} > \tilde{b}$;

If $H'(\tilde{a}) < H'(\tilde{b})$, then \tilde{a} is smaller than \tilde{b} , denoted by $\tilde{a} < \tilde{b}$;

If $H'(\tilde{a}) = H'(\tilde{b})$, then \tilde{a} and \tilde{b} represent the same information, denoted by $\tilde{a} = \tilde{b}$.

Theorem 3.1 Let $\tilde{a} = \langle T_a(x), I_a(x), F_a(x) \rangle$ be an SVNE, then the score function $S(\tilde{a}) = (T_a(x) - F_a(x))(1 - I_a(x))$, the sub-score function $S'(\tilde{a}) = T_a(x) - F_a(x)$ and the sub-accuracy function $H'(\tilde{a}) = T_a(x) + F_a(x)$ should satisfy the following properties.

$$(1) -1 \leq S(\tilde{a}) \leq 1;$$

$$(2) -1 \leq S'(\tilde{a}) \leq 1;$$

$$(3) 0 \leq H'(\tilde{a}) \leq 1.$$

Definition 3.5 An NFPR \tilde{A} on a fixed set $X = \{x_1, x_2, \dots, x_n\}$ is represented by a matrix

$\tilde{A} = (\tilde{a}_{ij})_{n \times n} \subset X \times X$ where $\tilde{a}_{ij} = \langle T_{\tilde{a}_{ij}}(x_{ij}), I_{\tilde{a}_{ij}}(x_{ij}), F_{\tilde{a}_{ij}}(x_{ij}) \rangle$ for any $i, j \in \{1, 2, \dots, n\}$. For convenience,

we let $\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$ for any $i, j \in \{1, 2, \dots, n\}$, where \tilde{a}_{ij} is an SVNE composed by the true degree T_{ij} , the indeterministic degree I_{ij} and the false degree F_{ij} of x_i preferred to x_j , respectively.

$\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$ should also satisfy the following characteristics:

$$T_{ij} = F_{ji}, F_{ij} = T_{ji}, I_{ij} = I_{ji}, T_{ii} = F_{ii} = 0.5 \text{ and } I_{ii} = 0 \text{ for any } i, j \in \{1, 2, \dots, n\}. \quad (5)$$

Definition 3.6 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an NFPR where $\tilde{a}_{ij} = \langle T_{\tilde{a}_{ij}}(x_{ij}), I_{\tilde{a}_{ij}}(x_{ij}), F_{\tilde{a}_{ij}}(x_{ij}) \rangle$ represented as

$\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$. \tilde{A} is additive consistent if it satisfies the following additive transitivity

$$T_{ij}(1 - I_{ij}) + T_{jk}(1 - I_{jk}) + T_{ki}(1 - I_{ki}) = T_{kj}(1 - I_{kj}) + T_{ji}(1 - I_{ji}) + T_{ik}(1 - I_{ik}) \text{ for any } i, j, k \in \{1, 2, \dots, n\}. \quad (6)$$

As $T_{ij} = F_{ji}$, $F_{ij} = T_{ji}$, $I_{ij} = I_{ji}$ for any $i, j \in \{1, 2, \dots, n\}$, it follows from Eq. (6) that

$$F_{ij}(1 - I_{ij}) + F_{jk}(1 - I_{jk}) + F_{ki}(1 - I_{ki}) = F_{kj}(1 - I_{kj}) + F_{ji}(1 - I_{ji}) + F_{ik}(1 - I_{ik}) \text{ for any } i, j, k \in \{1, 2, \dots, n\}. \quad (7)$$

In addition, if there exists $I_{ij} = 0$ in all SVNES $\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$ for any $i, j, k \in \{1, 2, \dots, n\}$, then

the NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ is equivalent to the IPR, and Eq. (6) and Eq. (7) are reduced to Eq. (3) and Eq. (4).

According to the Definition 3.4, we can get the following property.

Theorem 3.2 An NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ with $\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$ is additive consistent if and only if $S(\tilde{a}_{ij}) = S(\tilde{a}_{ik}) - S(\tilde{a}_{jk})$ for any $i, j, k \in \{1, 2, \dots, n\}$.

Theorem 3.2 provides an easy method to tell whether an NFPR satisfies the additive consistency or not.

According to Theorem 3.2, it's obvious that the additive consistency for an NFPR is too strict to satisfy in the realistic world. So we give another definition of consistency for NFPR, namely acceptable consistency, which can be easily accepted.

Definition 3.7 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an NFPR, $S(\tilde{a}_{ij})$ the score function of \tilde{a}_{ij} obtained by directly comparing alternatives x_i and x_j , and $S(\tilde{a}_{ik}) - S(\tilde{a}_{jk})$ the difference between the scores of neutrosophic fuzzy preference values derived by comparing them with an intermediate alternative x_k where $k \neq i, j$. Then the absolute mean deviation (AMD) ε_{ij} is defined as

$$\varepsilon_{ij} = \frac{1}{n-2} \sum_{k=1, k \neq i, j}^n |S(\tilde{a}_{ij}) - S(\tilde{a}_{ik}) + S(\tilde{a}_{jk})|. \quad (8)$$

According to the Definition 3.4 and Eq. (5), $S(\tilde{a}_{ik}) = (T_{ik} - F_{ik})(1 - I_{ik})$ and $S(\tilde{a}_{jk}) = (F_{jk} - T_{jk})(1 - I_{jk}) = -S(\tilde{a}_{kj})$. Thus, Eq. (8) is equal to the following Eq. (9).

$$\varepsilon_{ij} = \frac{1}{n-2} \sum_{k=1, k \neq i, j}^n |S(\tilde{a}_{ij}) + S(\tilde{a}_{jk}) + S(\tilde{a}_{ki})|. \quad (9)$$

Definition 3.8 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an NFPR, then $CI(\tilde{A})$ is the consistency index for \tilde{A} as follows

$$CI(\tilde{A}) = 1 - \frac{1}{3n(n-1)(n-2)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n |S(\tilde{a}_{ij}) + S(\tilde{a}_{jk}) + S(\tilde{a}_{ki})|. \quad (10)$$

For convenience, we let $\dot{S}(\tilde{A}) = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n |S(\tilde{r}_{ij}) + S(\tilde{r}_{jk}) + S(\tilde{r}_{ki})|$, then Eq. (10) can be written as

$CI(\tilde{A}) = 1 - \frac{1}{3n(n-1)(n-2)} \dot{S}(\tilde{A})$. It is clear that $0 \leq CI(\tilde{A}) \leq 1$, and the greater the $CI(\tilde{A})$, the more consistent the \tilde{A} . In particular, if $CI(\tilde{A}) = 1$ which is equal to $\varepsilon_{ij} = 0$ for any $i, j \in \{1, 2, \dots, n\}$, the NFPR \tilde{A} is the additive consistent; otherwise, \tilde{A} does not satisfy the additive consistency.

From the Definition 3.4, we conclude that $S(\tilde{r}_{ij}) + S(\tilde{r}_{jk}) + S(\tilde{r}_{ki})$ is equal to $T_{ij}(1-I_{ij}) - F_{ij}(1-I_{ij}) + T_{jk}(1-I_{jk}) - F_{jk}(1-I_{jk}) + T_{ki}(1-I_{ki}) - F_{ki}(1-I_{ki})$. Since $T_{ij} = F_{ji}$, $F_{ij} = T_{ji}$ in the NFPR \tilde{A} for any $i, j \in \{1, 2, \dots, n\}$, Eq. (10) can be represented as

$$CI(\tilde{A}) = 1 - \frac{1}{3n(n-1)(n-2)} \dot{T}(\tilde{A}),$$

where $\dot{T}(\tilde{A}) = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n |T_{ij}(1-I_{ij}) + T_{jk}(1-I_{jk}) + T_{ki}(1-I_{ki}) - T_{ji}(1-I_{ji}) - T_{kj}(1-I_{kj}) - T_{ik}(1-I_{ik})|$. (11)

$$\text{and as } CI(\tilde{A}) = 1 - \frac{1}{3n(n-1)(n-2)} \dot{F}(\tilde{A}),$$

where $\dot{F}(\tilde{A}) = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n |F_{ji}(1-I_{ji}) + F_{kj}(1-I_{kj}) + F_{ik}(1-I_{ik}) - F_{ij}(1-I_{ij}) - F_{jk}(1-I_{jk}) - F_{ki}(1-I_{ki})|$. (12)

Since the additive consistency for NFPR is too strict, so we introduce the following acceptable consistency in order to check the consistency levels in GDM problem.

Definition 3.9 Let $CI(\tilde{A})$ be the consistency index for an NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ and $0 \leq \theta \leq 1$ be an acceptable consistency threshold, then NFPR \tilde{A} is acceptably consistent if it satisfies $CI(\tilde{A}) \geq \theta$; otherwise, \tilde{A} is an unacceptably consistent NFPR. In addition, the greater the value of θ , the stricter of the consistency can be for \tilde{A} . The acceptable consistency is especially equal to the additive consistency when $\theta = 1$. DMs could choose an appropriate value of θ to construct a reasonable acceptable consistency. In general, it is suggested that DMs should set $\theta \in [0.5, 1]$, and the value of θ should be appropriately reduced with a large value of n .

Definition 3.10 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n} = \langle (T_{aij}, I_{aij}, F_{aij}) \rangle_{n \times n}$ and $\tilde{B} = (\tilde{b}_{ij})_{n \times n} = \langle (T_{bij}, I_{bij}, F_{bij}) \rangle_{n \times n}$ be two

NFPRs, then the mean absolute deviation (MAD) between \tilde{A} and \tilde{B} can be computed as follows

$$MAD(\tilde{A}, \tilde{B}) = \frac{1}{2n(n-1)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n \left(|T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})| + |F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij})| \right). \quad (13)$$

It is obvious that the smaller is the $MAD(\tilde{A}, \tilde{B})$, the closer \tilde{A} is to \tilde{B} . In particular, $\tilde{A} = \tilde{B}$ when $MAD(\tilde{A}, \tilde{B}) = 0$.

Theorem 3.3 If $MAD(\tilde{A}, \tilde{B})$ is the MAD between two NFPRs $\tilde{A} = (\tilde{a}_{ij})_{n \times n} = \left(\langle T_{aij}, I_{aij}, F_{aij} \rangle \right)_{n \times n}$ and $\tilde{B} = (\tilde{b}_{ij})_{n \times n} = \left(\langle T_{bij}, I_{bij}, F_{bij} \rangle \right)_{n \times n}$, it should satisfy the following properties.

(a) $0 \leq MAD(\tilde{A}, \tilde{B}) \leq 1$;

(b) $MAD(\tilde{A}, \tilde{B}) = MAD(\tilde{B}, \tilde{A})$;

(c) The MAD between \tilde{A} and \tilde{B} can be written as

$$MAD(\tilde{A}, \tilde{B}) = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n |T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})|. \quad (14)$$

4. An approach for improving consistency of NFPRs

MCGDM problems with vague information are widespread in the real world and are therefore the foci of many scholars [56-60]. Different extensions of PRs have been developed because of their effectiveness in expressing the DM's preferences [32,48,61]. Although in the process of MCGDM the most common method to improve an NFPR with unacceptable consistency is to let DMs update the original information, it is hard for the DMs to adjust their original judgments to real life. To solve this conundrum, we have devised a method to improve the consistency of NFPRs which retains maintain the original information as much as possible. The innovations of this paper include: (i) NFPRs to help DMs express their preferences more accurately, (ii) a method to improve consistency of NFPRs, and (iii) a novel method to obtain the weights of criteria based on the preference values of DMs in MCGDM problems.

Definition 4.1 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an NFPR with $\tilde{a}_{ij} = \langle T_{ij}, I_{ij}, F_{ij} \rangle$, then the NFPR $\hat{A} = (\hat{a}_{ij})_{n \times n}$ is an additive consistent NFPR if $\hat{a}_{ij} = \langle \hat{T}_{ij}, \hat{I}_{ij}, \hat{F}_{ij} \rangle$ satisfies $\hat{T}_{ij} \geq 0$, $\hat{I}_{ij} \geq 0$ and

$$\begin{aligned} \hat{T}_{ij}(1-\hat{I}_{ij}) &= \frac{1}{2n} \left(\sum_{l=1}^n (T_{il}(1-I_{il}) - T_{jl}(1-I_{jl})) - \sum_{l=1}^n (T_{li}(1-I_{li}) - T_{lj}(1-I_{lj})) \right) + 0.5(T_{ij}(1-I_{ij}) + T_{ji}(1-I_{ji})) \\ \hat{F}_{ij}(1-\hat{I}_{ij}) &= \frac{1}{2n} \left(\sum_{l=1}^n (F_{il}(1-I_{il}) - F_{jl}(1-I_{jl})) - \sum_{l=1}^n (F_{li}(1-I_{li}) - F_{lj}(1-I_{lj})) \right) + 0.5(F_{ij}(1-I_{ij}) + F_{ji}(1-I_{ji})) \\ \hat{I}_{ij} &= \begin{cases} 1 - \hat{T}_{ij}(1-\hat{I}_{ij})/\hat{T}_{ij}, & \hat{T}_{ij}(1-\hat{I}_{ij})/\hat{T}_{ij} \leq 1, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ 0, & \text{otherwise} \end{cases} \\ \hat{T}_{ij} &= \begin{cases} T_{ij}, & \hat{T}_{ij}(1-\hat{I}_{ij})/\hat{T}_{ij} \leq 1, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ \hat{T}_{ij}(1-\hat{I}_{ij}), & \text{otherwise} \end{cases} \\ \hat{F}_{ij} &= \frac{\hat{F}_{ij}(1-\hat{I}_{ij})}{1-\hat{I}_{ij}}, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ \hat{I}_{ij} &= \hat{I}_{ji}, \hat{T}_{ij} = \hat{F}_{ji}, \hat{F}_{ij} = \hat{T}_{ji} \text{ for any } i < j \in \{1, 2, \dots, n\}. \end{aligned} \quad (15)$$

In addition, if there exists $\hat{T}_{ij} < 0$ for some $i, j \in \{1, 2, \dots, n\}$ in $\hat{A} = (\hat{a}_{ij})_{n \times n}$, it is not an NFPR. In this case, all of the values of \hat{T}_{ij} should be converted to an interval $[0, 1]$. So we give the following definition of the converted values based on [29].

Definition 4.2 Let $\hat{A} = (\hat{a}_{ij})_{n \times n}$ with $\hat{a}_{ij} = \langle \hat{T}_{ij}, \hat{I}_{ij}, \hat{F}_{ij} \rangle$ the matrix obtained from the NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ based on Definition 4.1. Then the matrix $\tilde{A}' = (\tilde{a}'_{ij})_{n \times n}$ is called a rectified matrix with $\tilde{a}'_{ij} = \langle \tilde{T}'_{ij}, \tilde{I}'_{ij}, \tilde{F}'_{ij} \rangle$ if the converted values are as follows.

$$\begin{aligned} \tilde{T}'_{ij}(1-\tilde{I}'_{ij}) &= \frac{\hat{T}_{ij}(1-\hat{I}_{ij})+t}{1+2t}, \quad \tilde{F}'_{ij}(1-\tilde{I}'_{ij}) = \frac{\hat{F}_{ij}(1-\hat{I}_{ij})+t}{1+2t}, \text{ for any } i, j \in \{1, 2, \dots, n\} \\ \text{where } t &= \begin{cases} 0, & \hat{T}_{ij}(1-\hat{I}_{ij}) \geq 0 \\ \max\{\hat{T}_{ij}(1-\hat{I}_{ij})\}, & \hat{T}_{ij}(1-\hat{I}_{ij}) < 0 \end{cases}, \text{ for any } i, j \in \{1, 2, \dots, n\} \\ \tilde{I}'_{ij} &= \begin{cases} 1 - \tilde{T}'_{ij}(1-\tilde{I}'_{ij})/\hat{T}_{ij}, & \tilde{T}'_{ij}(1-\tilde{I}'_{ij})/\hat{T}_{ij} \leq 1, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ 0, & \text{otherwise} \end{cases} \\ \tilde{T}'_{ij} &= \begin{cases} \hat{T}_{ij}, & \tilde{T}'_{ij}(1-\tilde{I}'_{ij})/\hat{T}_{ij} \leq 1, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ \tilde{T}'_{ij}(1-\tilde{I}'_{ij}), & \text{otherwise} \end{cases} \end{aligned}$$

$$\tilde{F}_{ij}' = \frac{\tilde{F}_{ij}'(1 - \tilde{I}_{ji}')}{1 - \tilde{I}_{ji}'}, \text{ for any } i \geq j \in \{1, 2, \dots, n\}$$

$$\tilde{T}_{ij}' = \tilde{F}_{ji}', \quad \tilde{F}_{ij}' = \tilde{T}_{ji}', \quad \tilde{I}_{ij}' = \tilde{I}_{ji}', \text{ for any } i < j \in \{1, 2, \dots, n\}. \quad (16)$$

Theorem 4.1 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an NFPR and the derived matrix $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ is converted based on Eq. (15) and Eq. (16), then $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ is an additive consistent NFPR.

Theorem 4.2 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an additive consistent NFPR and $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ the derived matrix obtained from \tilde{A} based on Definition 4.2, then $\tilde{A} = \tilde{A}'$.

Definition 4.3 Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ is an NFPR with $\tilde{a}_{ij} = \langle \tilde{T}_{ij}, \tilde{I}_{ij}, \tilde{F}_{ij} \rangle$ and $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ is the derived additive consistent matrix where $\tilde{a}_{ij}' = \langle \tilde{T}_{ij}', \tilde{I}_{ij}', \tilde{F}_{ij}' \rangle$, then $\tilde{A}(\lambda) = (\tilde{a}_{ij}(\lambda))$ is a weighted averaging matrix if $\tilde{a}_{ij}(\lambda) = \langle \tilde{T}_{ij}(\lambda), \tilde{I}_{ij}(\lambda), \tilde{F}_{ij}(\lambda) \rangle$ satisfies

$$\begin{aligned} \tilde{T}_{ij}(\lambda)(1 - \tilde{I}_{ij}(\lambda)) &= (1 - \lambda)\tilde{T}_{ij}(1 - \tilde{I}_{ij}) + \lambda\tilde{T}_{ij}'(1 - \tilde{I}_{ij}') \\ \tilde{T}_{ij}(\lambda) &= \begin{cases} 1 - \tilde{T}_{ij}(\lambda)(1 - \tilde{I}_{ij}(\lambda)) / \tilde{T}_{ij}, & \tilde{T}_{ij}(\lambda)(1 - \tilde{I}_{ij}(\lambda)) / \tilde{T}_{ij} \leq 1 \\ 0, & \text{otherwise} \end{cases}, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ \tilde{T}_{ij}(\lambda) &= \begin{cases} \tilde{T}_{ij}, & \tilde{T}_{ij}(\lambda)(1 - \tilde{I}_{ij}(\lambda)) / \tilde{T}_{ij} \leq 1 \\ \tilde{T}_{ij}(\lambda)(1 - \tilde{I}_{ij}(\lambda)), & \text{otherwise} \end{cases}, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \\ \tilde{F}_{ij}(\lambda) &= \frac{\tilde{F}_{ij}(\lambda)(1 - \tilde{I}_{ji}(\lambda))}{1 - \tilde{I}_{ji}(\lambda)}, \text{ for any } i \geq j \in \{1, 2, \dots, n\} \end{aligned}$$

$$\tilde{T}_{ij}(\lambda) = \tilde{F}_{ji}(\lambda), \quad \tilde{F}_{ij}(\lambda) = \tilde{T}_{ji}(\lambda), \quad \tilde{I}_{ij}(\lambda) = \tilde{I}_{ji}(\lambda), \text{ for any } i < j \in \{1, 2, \dots, n\}. \quad (17)$$

Theorem 4.3 If $\tilde{A}(\lambda) = (\tilde{a}_{ij}(\lambda))$ is a weighted averaging matrix obtained from an original NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ and its derived additive consistent NFPR $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ based on Definition 4.3, then $\tilde{A}(\lambda)$ is still an NFPR.

Theorem 4.4 Let $0 \leq \theta \leq 1$ be an acceptable consistency threshold, and $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ and $\tilde{A}' = (\tilde{a}_{ij}')_{n \times n}$ be the original NFPR and the derived consistent NFPR, respectively, then the matrix $\tilde{A}(\lambda) = (\tilde{a}_{ij}(\lambda))$ is

an acceptably consistent NFPR if $\frac{\theta - CI(\tilde{A})}{1 - CI(\tilde{A})} \leq \lambda \leq 1$.

Based on the above definitions, the process to construct an acceptably consistent NFPR is summarized as follows:

Step 1. Construct the additive consistent NFPR $\hat{A} = (\hat{a}_{ij})_{n \times n}$ based on an NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ according to Eq. (15).

Step 2. Convert $\hat{A} = (\hat{a}_{ij})_{n \times n}$ into a rectified matrix $\tilde{A}' = (\tilde{a}'_{ij})_{n \times n}$ as per Eq. (16).

Step 3. Calculate the weight $\lambda_0 = \frac{\theta - CI(\tilde{A})}{1 - CI(\tilde{A})}$, where $0 \leq \theta \leq 1$ is the acceptable consistency threshold decided by the DM.

Step 4. As per the Definition 4.3, build the improved acceptably consistent NFPR $\tilde{A}(\lambda) = (\tilde{a}_{ij}(\lambda))$.

From **Definition 3.10** and **Definition 4.3**, we can clearly see that the MAD value reflects similarity between two NFPRs and it is appropriate for several individual NFPRs under one criterion. For several NFPRs under different criteria, the bigger MAD value between one NFPR and its acceptably consistent NFPR implies the higher consistency of this NFPR, which implies that DMs are more consistent on their preferences under this criterion. Since the criterion that has less disagreements deserves higher weight, then it is reasonable to apply MAD value for solving MCGDM problems. Therefore, we applied the MAD value to obtain the weight of criteria in MCGDM problem.

5. An MCGDM method based on the consistency of NFPRs

In this section we propose a systematic MCGDM method under the environment of NFPRs, including the measuring consistency for the original preference matrices thus improving the consistency for the NFPRs with unacceptable consistency, integrating those NFPRs and ranking the alternatives.

5.1 Aggregation operators for NFPRs

The aim of this section is to develop some aggregation operators which are essential for aggregating

the NFPRs in the MCGDM problems.

Definition 5.1. Let $\tilde{A}_z = (\tilde{a}_{zij})_{n \times n}$ be an NFPR where $\tilde{a}_{zij} = \langle T_{\tilde{a}_{zij}}, I_{\tilde{a}_{zij}}, F_{\tilde{a}_{zij}} \rangle$ and $W = (w_1, w_2, \dots, w_k)^T$

be the weight vector with $w_z \in [0,1]$ and $\sum_{z=1}^k w_z = 1$, then the neutrosophic fuzzy preference relation

weighted averaging (NFPRWA) operator is as follows:

$$NPRWA(\tilde{A}_1, \tilde{A}_2, \dots, \tilde{A}_k) = \left(\bigoplus_{z=1}^k (w_z \tilde{a}_{zij}) \right)_{n \times n} = \left\langle \left\langle \sum_{z=1}^k w_z T_{\tilde{a}_{zij}}, \sum_{z=1}^k w_z I_{\tilde{a}_{zij}}, \sum_{z=1}^k w_z F_{\tilde{a}_{zij}} \right\rangle \right\rangle_{n \times n}. \quad (18)$$

Definition 5.2 Let $\tilde{A}_z = (\tilde{a}_{zij})_{n \times n}$ be an NFPR with $\tilde{a}_{zij} = \langle T_{\tilde{a}_{zij}}, I_{\tilde{a}_{zij}}, F_{\tilde{a}_{zij}} \rangle$, then the neutrosophic fuzzy

preference relation induced ordered weighted averaging (NFPRIOWA) operator is defined as:

$$NPRIOWA(\langle H_1, \tilde{A}_{\sigma(1)} \rangle, \langle H_2, \tilde{A}_{\sigma(2)} \rangle, \dots, \langle H_k, \tilde{A}_{\sigma(k)} \rangle) = \left(\bigoplus_{z=1}^k (w_z \tilde{a}_{\sigma(z)ij}) \right)_{n \times n} \\ = \left\langle \left\langle \sum_{z=1}^k w_z T_{\tilde{a}_{\sigma(z)ij}}, \sum_{z=1}^k w_z I_{\tilde{a}_{\sigma(z)ij}}, \sum_{z=1}^k w_z F_{\tilde{a}_{\sigma(z)ij}} \right\rangle \right\rangle_{n \times n}. \quad (19)$$

where $\langle H_1, \tilde{A}_{\sigma(1)} \rangle, \langle H_2, \tilde{A}_{\sigma(2)} \rangle, \dots, \langle H_k, \tilde{A}_{\sigma(k)} \rangle$ is a set of OWA pairs, $W = (w_1, w_2, \dots, w_k)^T$ is the

associated weight vector with $w_z \in [0,1]$ and $\sum_{z=1}^k w_z = 1$, σ is the permutation of $\{1,2,\dots,k\}$ with

$H_{\sigma(z)} \geq H_{\sigma(z+1)}$ for any $z \in \{1,2,\dots,k\}$ and $\tilde{A}_{\sigma(z)}$ is a reordering of \tilde{A}_z as per the decreasing order of $\{H_1, H_2, \dots, H_k\}$.

In particular, if the order of \tilde{A}_z is the same as that of $\tilde{A}_{\sigma(k)}$, the NFPRIOWA operator is reduced to the NFPRWA operator and if $W = (1/k, 1/k, \dots, 1/k)^T$, the NFPRWA operator is equal to the neutrosophic fuzzy preference relation averaging (NFPRWA) operator as

$$NPRA(\tilde{A}_1, \tilde{A}_2, \dots, \tilde{A}_k) = \left(\bigoplus_{z=1}^k \left(\frac{1}{k} \tilde{a}_{zij} \right) \right)_{n \times n} = \left\langle \left\langle \sum_{z=1}^k \frac{1}{k} T_{\tilde{a}_{zij}}, \sum_{z=1}^k \frac{1}{k} I_{\tilde{a}_{zij}}, \sum_{z=1}^k \frac{1}{k} F_{\tilde{a}_{zij}} \right\rangle \right\rangle_{n \times n}. \quad (20)$$

In addition, we define the ordering inducing value H_z , accounts for both the MAD value $MAD(\tilde{A}_z, \tilde{A}_z(\lambda))$ and the consistency index value $CI(\tilde{A}_z(\lambda))$, as follows

$$H_z = \frac{1}{2}CI(\tilde{A}_z(\lambda)) + \frac{1}{2}(1 - MAD(\tilde{A}_z, \tilde{A}_z(\lambda))) \text{ where } p=1,2,\dots,k. \quad (21)$$

On the basis of H_z , the associated weight vector is defined as

$$w_t = \begin{cases} \left(\frac{H_{\sigma(1)}}{\sum_{z=1}^k H_{\sigma(1)}} \right)^\beta, & t=1 \\ \left(\frac{\sum_{z=1}^t H_{\sigma(1)}}{\sum_{z=1}^k H_{\sigma(1)}} \right)^\beta - \left(\frac{\sum_{z=1}^{t-1} H_{\sigma(1)}}{\sum_{z=1}^k H_{\sigma(1)}} \right)^\beta, & t=2,3,\dots,k \end{cases}. \quad (22)$$

where $0 \leq \beta \leq 1$ is a parameter controlling the value of H_1 : if $\beta=1$, Eq. (19) is based on the normalized induced value aggregation method for the NFPRs, and if $\beta=0$, Eq. (19) is based on the maximum inducing aggregation method for the NFPRs. It is obvious that if $H_{\sigma(1)} \geq H_{\sigma(2)} \geq \dots \geq H_{\sigma(k)}$, then $w_{\sigma(1)} \geq w_{\sigma(2)} \geq \dots \geq w_{\sigma(k)}$, so the higher the value H_z , the greater the weight w_z is.

5.2 An MCGDM method with NFPRs

Based on the above definitions, we have detailed the steps of an MCGDM method with the NFPRs as shown below. The scenario is that t experts are asked to give their own preference value over n alternatives under k criteria.

Step 1. Compute the consistency level $CI(\tilde{A}_{z_p})$ for NFPRs $\tilde{A}_{z_p} = (\tilde{a}_{z_p ij})_{n \times n}$ where $\tilde{a}_{z_p ij} = \langle T_{\tilde{a}_{z_p ij}}, I_{\tilde{a}_{z_p ij}}, F_{\tilde{a}_{z_p ij}} \rangle$ and \tilde{A}_{z_p} is the preference value matrix provided by the p th DM under the z th attribute about n alternatives based on Eqs. (10-12), where $i, j=1,2,\dots,n$, $p=1,2,\dots,t$ and $z=1,2,\dots,k$.

Step 2. For every \tilde{A}_{z_p} , if $CI(\tilde{A}_{z_p}) \geq \theta$, let $\tilde{A}_{z_p}(\lambda) = \tilde{A}_{z_p}$; otherwise, return the original matrix \tilde{A}_{z_p} to the DMs and go back to Step 1. If it is not feasible for the DMs to update \tilde{A}_{z_p} , then calculate the weighted averaging matrix $\tilde{A}_{z_p}(\lambda) = (\tilde{a}_{z_p ij}(\lambda))$ as per Eq. (17).

Step 3. Aggregate NFPRs $\tilde{A}_{z_p}(\lambda)$ for any $z \in \{1,2,\dots,k\}$ into k NFPRs $\tilde{A}_z = (\tilde{a}_{z ij})_{n \times n}$ using the

NFPRWA operator with given weights of t experts, as per Eq. (18).

Step 4. Calculate the MAD value $MAD(\tilde{A}_z, \tilde{A}_z(\lambda))$ where $z = 1, 2, \dots, k$ according to Eqs. (13-14).

Step 5. Compute the ordering inducing value H_z by combing both the $CI(\tilde{A}_z(\lambda))$ and $MAD(\tilde{A}_z, \tilde{A}_z(\lambda))$, based on Eq. (21).

Step 6. Get the value of associated weights $W = (w_1, w_2, \dots, w_k)^T$ according to Eq. (22).

Step 7. Aggregate all the NFPRs $\tilde{A}_z(\lambda)$ for any $z \in \{1, 2, \dots, k\}$ into a group NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ using the NFPRIOWA operator as per Eq. (19).

Step 8. Calculate the score function of \tilde{a}_{ij} for any $i, j \in \{1, 2, \dots, n\}$, denoted as $S(\tilde{a}_{ij})$ as per

Definition 3.4, and get $S(A_i) = \sum_{j=1}^n S(\tilde{a}_{ij})$ to rank the alternatives. If there exists $S(A_i) = S(A_j)$ where

$i \neq j \in \{1, 2, \dots, n\}$, rank the alternatives by computing the sub-score function and sub-accuracy function in the same way.

5.3 The model of MCGDM method with NFPRs

In this section we describe the model of proposed MCGDM method with NFPRs as depicted in Fig. 1 as follows.

INSERT FIGURE 1 HERE

6. MCGDM-NFPRs Model for Medical Tourism Destination Selection

In this section, we verify flexibility and practicability of our proposed MCGDM-NFPRs model by using Case 1 and Case 2, from two different aspects. The backgrounds and data of two cases are described in Section 6.1, followed by Section 6.2 and Section 6.3 show the computational process and result of two cases, respectively. The results are then discussed in Section 6.4.

6.1. Background

The proposed method is conducted to evaluate some medical tourism destinations and select the most appropriate one. The data sources, data processing and objectives of two cases are different and described as follows.

- *Data sources:*

- For Case 1, the primary and secondary data were collected from patients, policy makers, doctors, and tours and hospitality managers during the period 2014-2015, including primary data and secondary data. Roy et al. [14] collected the data in order to select the most suitable medical tourism destinations in India. Six experts were invited to give their linguistic decision for nine cities in India under seven criteria.
- The data in Case 2 is adapted from Wang et al. [29] and the original data was in the form of intuitionistic fuzzy preference values. Four experts were asked to give their own preferences about four alternatives, independently.

- *Data processing:*

- The original data [14] in Case 1 was in the form of linguistic decision value for each alternative, which is different from the preference value in our method. Therefore we transformed the experts based decision matrix to 42 neutrosophic preference matrices $\tilde{A}_{z_p} = (\tilde{a}_{z_p ij})_{n \times n}$ where $z = 1, 2, \dots, 7$, $p = 1, 2, \dots, 6$ and $i, j = 1, 2, \dots, 9$.
- In Case 2, the original data [29] was composed by four intuitionistic preference matrices, representing the independent assessments of the four experts. By comparing every pair of the four alternatives, we adapted it to neutrosophic preference matrices $\tilde{A}_z = (\tilde{a}_{z ij})_{n \times n}$ where $z = 1, 2, \dots, 4$ and $i, j = 1, 2, \dots, 4$.

● *Objectives:*

- To verify the validity and stability of proposed method in the evaluation and selection of medical tourism destinations, especially the usefulness of MAD value in MCGDM problems, by Case 1.
- To demonstrate the advantage of examining and constructing the logical consistency for patient-travelers, and the necessity of using NFPRs, by Case 2.
- To discover the future research directions, according to the results of comparison with other algorithms in the two cases.

6.2. The illustration of proposed method (Case 1)

The data resource has been introduced in Section 6.1. Seven maximizing criteria $\{C_1, C_2, C_3, C_4, C_5, C_6, C_7\}$ were chosen and divided into three groups: (1) strengthening of the infrastructure wherein C_1 is quality of infrastructure of the medical establishments, C_2 represents traffic convenience and population statistics and C_3 is the information infrastructure and circulation channels; (2) strengthening of the services for medical tourism in which C_4 is the supply of skilled technological workers and C_5 is the quality of medical operators and consultancy centers; and (3) the planning and policies for medical tourism where C_6 and C_7 represent progress plan, corresponding laws and policies respectively. In consideration of the above criteria, six experts were invited to give their linguistic decision for nine cities in India including Bangalore, Chennai, Delhi, Hyderabad, Jaipur, Kolkata, Mumbai, Pune, and Kochi.

As described in Section 6.1, the values of experts based decision matrix were expressed by a 9-point scale system, where 1 stands for "very low", 3 stands for "low", 5 for "moderate", and 7 and 9

INSERT TABLES (1, 2) HERE

Furthermore, because of the original 42 matrices, the aggregated 7 matrices (under 7 attributes) and the final aggregated matrix were all adapted to satisfy consistency and the results of proposed method were different to that of rough AHP-MABAC. For example, if the original 42 matrices didn't accept normalization, the ranking would be $A_2 > A_3 > A_1 > A_8 > A_9 > A_4 = A_7 > A_6 > A_5$. These rankings are depicted in Fig. 2.

INSERT FIGURE 2 HERE

6.3. The illustration of proposed method (Case 2)

The resource and processing of data have been described in Section 6.1. A group of four medical tourism tourists represented as $D = \{d_1, d_2, d_3, d_4\}$ were asked to express their preference values based on their own knowledge and experience. They expressed their assessments of one city (destination) over another among a total of four cities $X = \{x_1, x_2, \dots, x_4\}$, using NFPRs $\tilde{A}_z = (\tilde{a}_{zij})_{n \times n}$ with $\tilde{a}_{zij} = \langle T_{\tilde{a}_{zij}}, I_{\tilde{a}_{zij}}, F_{\tilde{a}_{zij}} \rangle$ where $z \in \{1, 2, 3, 4\}$ and $i, j \in \{1, 2, 3, 4\}$. The original four matrices are shown as follows.

$$\tilde{A}_1 = \begin{bmatrix} \langle 0.5, 0, 0.5 \rangle & \langle 0.9, 0.5, 0.5 \rangle & \langle 0.375, 0.2, 0.5 \rangle & \langle 0.8, 0.5, 0.9 \rangle \\ \langle 0.5, 0.5, 0.9 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.4, 0.5, 0.7 \rangle & \langle 0.5, 0.4, 0.75 \rangle \\ \langle 0.5, 0.2, 0.375 \rangle & \langle 0.7, 0.5, 0.4 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.7, 0.5, 0.9 \rangle \\ \langle 0.9, 0.5, 0.8 \rangle & \langle 0.75, 0.4, 0.5 \rangle & \langle 0.9, 0.5, 0.7 \rangle & \langle 0.5, 0, 0.5 \rangle \end{bmatrix}$$

$$\tilde{A}_2 = \begin{bmatrix} \langle 0.5, 0, 0.5 \rangle & \langle 0.2, 0.1, 0.4 \rangle & \langle 0.35, 0, 0.3 \rangle & \langle 0.45, 0, 0.25 \rangle \\ \langle 0.4, 0.1, 0.2 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.65, 0.2, 0.25 \rangle & \langle 0.35, 0, 0.45 \rangle \\ \langle 0.3, 0, 0.35 \rangle & \langle 0.25, 0.2, 0.65 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.3, 0, 0.45 \rangle \\ \langle 0.25, 0, 0.45 \rangle & \langle 0.45, 0, 0.35 \rangle & \langle 0.45, 0, 0.3 \rangle & \langle 0.5, 0, 0.5 \rangle \end{bmatrix}$$

$$\tilde{A}_3 = \begin{bmatrix} \langle 0.5,0,0.5 \rangle & \langle 0.4,0,0.55 \rangle & \langle 0.05,0,0.9 \rangle & \langle 0.1,0,0.8 \rangle \\ \langle 0.55,0,0.4 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.3,0,0.6 \rangle & \langle 0.05,0,0.85 \rangle \\ \langle 0.9,0,0.05 \rangle & \langle 0.6,0,0.3 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.95,0,0 \rangle \\ \langle 0.8,0,0.1 \rangle & \langle 0.85,0,0.05 \rangle & \langle 0,0,0.95 \rangle & \langle 0.5,0,0.5 \rangle \end{bmatrix}$$

$$\tilde{A}_4 = \begin{bmatrix} \langle 0.5,0,0.5 \rangle & \langle 0.1,0,0.7 \rangle & \langle 0.8,0,0.1 \rangle & \langle 0.5,0,0.4 \rangle \\ \langle 0.7,0,0.1 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.7,0,0.1 \rangle & \langle 0.3,0,0 \rangle \\ \langle 0.1,0,0.8 \rangle & \langle 0.1,0,0.7 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.8,0,0.1 \rangle \\ \langle 0.4,0,0.5 \rangle & \langle 0,0,0.3 \rangle & \langle 0.1,0,0.8 \rangle & \langle 0.5,0,0.5 \rangle \end{bmatrix}.$$

According to Eqs. (10-12), one can calculate the consistency level $CI(\tilde{A}_z)$ of every NFPR \tilde{A}_z , for $z = 1,2,3,4$. The result is shown as below:

$$CI(\tilde{A}_1) = 0.9583, \quad CI(\tilde{A}_2) = 0.905, \quad CI(\tilde{A}_3) = 0.7583, \quad CI(\tilde{A}_4) = 0.7167.$$

Let the acceptable consistency threshold $\theta = 0.9$, then based on the Definition 3.9, the NFPRs \tilde{A}_1 and \tilde{A}_2 are acceptably consistent. Therefore, $\tilde{A}_1(\lambda) = \tilde{A}_1$ and $\tilde{A}_2(\lambda) = \tilde{A}_2$.

On the other hand, because $CI(\tilde{A}_3) = 0.7583 < \theta = 0.9$ and $CI(\tilde{A}_4) = 0.7167 < \theta = 0.9$, one can get the transformation of \tilde{A}_3 and \tilde{A}_4 , represented as \hat{A}_3 and \hat{A}_4 , respectively. As per Eq. (15), there exists $\hat{I}_{442} = \hat{I}_{424} = -0.034$ in the matrix \hat{A}_4 . Based on Eq. (16), $t = 0.029$, then the rectified matrix $\tilde{A}_3' = (\tilde{a}_{3ij}')_{n \times n} = \hat{A}_3 = (\hat{a}_{3ij})_{n \times n}$ $\hat{A}_4' = (\hat{a}_{4ij}')_{n \times n}$ is constructed as follows:

$$\tilde{A}_3' = \begin{bmatrix} \langle 0.5,0,0.5 \rangle & \langle 0.5278,0.1136,0.55 \rangle & \langle 0.2275,0.1574,0.9 \rangle & \langle 0.4255,0.2656,0.8 \rangle \\ \langle 0.55,0.1136,0.5218 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.1792,0,0.7208 \rangle & \langle 0.4804,0.3235,0.85 \rangle \\ \langle 0.9,0.1574,0.2275 \rangle & \langle 0.7208,0,0.1792 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.6208,0,0.3292 \rangle \\ \langle 0.8,0.2656,0.4255 \rangle & \langle 0.85,0.3235,0.4804 \rangle & \langle 0.3292,0,0.6208 \rangle & \langle 0.5,0,0.5 \rangle \end{bmatrix}$$

$$\tilde{A}_4' = \begin{bmatrix} \langle 0.5,0,0.5 \rangle & \langle 0.5761,0.3644,0.7 \rangle & \langle 0.5276,0,0.3780 \rangle & \langle 0.7219,0.1929,0.4 \rangle \\ \langle 0.7,0.3644,0.5761 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.5197,0,0.2913 \rangle & \langle 0.3386,0,0 \rangle \\ \langle 0.3780,0,0.5276 \rangle & \langle 0.2913,0,0.5197 \rangle & \langle 0.5,0,0.5 \rangle & \langle 0.5078,0,0.3976 \rangle \\ \langle 0.4,0.1929,0.7219 \rangle & \langle 0,0,0.3386 \rangle & \langle 0.3976,0,0.5079 \rangle & \langle 0.5,0,0.5 \rangle \end{bmatrix}$$

As per Eq. (17) and Theorem 4.4, we can get

$$\tilde{T}_{3ij}(\lambda)(1 - \tilde{T}_{3ij}(\lambda)) = (1 - \lambda)\tilde{T}_{3ij}(1 - \tilde{T}_{3ij}) + \lambda\tilde{T}_{3ij}'(1 - \tilde{T}_{3ij}') = 0.414\tilde{T}_{3ij}(1 - \tilde{T}_{3ij}) + 0.586\tilde{T}_{3ij}'(1 - \tilde{T}_{3ij}') \quad \text{and}$$

$$\tilde{T}_{3ij}(\lambda)(1 - \tilde{T}_{3ij}(\lambda)) = (1 - \lambda)\tilde{T}_{3ij}(1 - \tilde{T}_{3ij}) + \lambda\tilde{T}_{3ij}'(1 - \tilde{T}_{3ij}') = 0.353\tilde{T}_{3ij}(1 - \tilde{T}_{3ij}) + 0.647\tilde{T}_{3ij}'(1 - \tilde{T}_{3ij}') \quad . \quad \text{Then the}$$

weighted averaging matrices $\tilde{A}_3(\lambda)$ and $\tilde{A}_4(\lambda)$ were obtained as below:

$$\tilde{A}_3(\lambda) = \begin{bmatrix} \langle 0.5, 0, 0.5 \rangle & \langle 0.4678, 0.0666, 0.55 \rangle & \langle 0.1466, 0.0923, 0.9 \rangle & \langle 0.2660, 0.1557, 0.8 \rangle \\ \langle 0.55, 0.0666, 0.4678 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.2292, 0, 0.6708 \rangle & \langle 0.2606, 0.1897, 0.85 \rangle \\ \langle 0.9, 0.0923, 0.1466 \rangle & \langle 0.6708, 0, 0.2292 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.7570, 0, 0.1930 \rangle \\ \langle 0.8, 0.1557, 0.2660 \rangle & \langle 0.85, 0.1897, 0.2606 \rangle & \langle 0.1930, 0, 0.7570 \rangle & \langle 0.5, 0, 0.5 \rangle \end{bmatrix}$$

$$\tilde{A}_4(\lambda) = \begin{bmatrix} \langle 0.5, 0, 0.5 \rangle & \langle 0.3562, 0.2358, 0.7 \rangle & \langle 0.6237, 0, 0.2799 \rangle & \langle 0.6324, 0.1248, 0.4 \rangle \\ \langle 0.7, 0.2358, 0.3562 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.5833, 0, 0.2238 \rangle & \langle 0.3250, 0, 0 \rangle \\ \langle 0.2799, 0, 0.6237 \rangle & \langle 0.2238, 0, 0.5833 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.6110, 0, 0.2926 \rangle \\ \langle 0.4, 0.1248, 0.6324 \rangle & \langle 0, 0, 0.3250 \rangle & \langle 0.2926, 0, 0.6110 \rangle & \langle 0.5, 0, 0.5 \rangle \end{bmatrix}$$

The two NFPRs $\tilde{A}_3(\lambda)$ and $\tilde{A}_4(\lambda)$ are acceptably consistent with the $CI(\tilde{A}_3(\lambda))=0.9$ and $CI(\tilde{A}_4(\lambda))=0.9$. The MAD values between \tilde{A}_z and $\tilde{A}_z(\lambda)$ where $z \in \{1, 2, 3, 4\}$ are then computed as below:

$$MAD(\tilde{A}_1(\lambda), \tilde{A}_1) = 0, \quad MAD(\tilde{A}_2(\lambda), \tilde{A}_2) = 0, \quad MAD(\tilde{A}_3(\lambda), \tilde{A}_3) = 0.11154, \quad MAD(\tilde{A}_4(\lambda), \tilde{A}_4) = 0.12033.$$

The value of H_z for any $z \in \{1, 2, 3, 4\}$ can be obtained by plugging $MAD(\tilde{A}_z(\lambda), \tilde{A}_z)$ and $CI(\tilde{A}_z(\lambda))$: $H_1 = 0.9792$, $H_2 = 0.9525$, $H_3 = 0.8942$, $H_4 = 0.8898$. Based on the value of H_z and Eq. (22), the associated weight vectors $W = (w_1, w_2, w_3, w_4)^T$ were calculated as shown in Table 3 and Fig. 3.

INSERT TABLE 3 AND FIGURE 3 HERE

We can see in Table 3 and Fig. 3 that the greater the value of β , the smaller the sum of the differences between the two value of weights w_i and w_{i+1} , where $i = 1, 2, 3$. In this example, we let $\beta = 1$, then the weights are $W = (0.264, 0.256, 0.241, 0.239)^T$. One can get the aggregated NFPR

$\tilde{G} = (\tilde{g}_{ij})_{n \times n}$ on the basis of W and permutation σ , written as

$$\tilde{G} = \begin{bmatrix} \langle 0.5, 0, 0.5 \rangle & \langle 0.486, 0.230, 0.534 \rangle & \langle 0.373, 0.075, 0.492 \rangle & \langle 0.542, 0.199, 0.590 \rangle \\ \langle 0.534, 0.230, 0.486 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.467, 0.183, 0.464 \rangle & \langle 0.362, 0.151, 0.518 \rangle \\ \langle 0.492, 0.075, 0.373 \rangle & \langle 0.464, 0.183, 0.467 \rangle & \langle 0.5, 0, 0.5 \rangle & \langle 0.590, 0.132, 0.469 \rangle \\ \langle 0.590, 0.199, 0.542 \rangle & \langle 0.518, 0.151, 0.362 \rangle & \langle 0.469, 0.132, 0.590 \rangle & \langle 0.5, 0, 0.5 \rangle \end{bmatrix}$$

As per Eq. (10), the consistency index of \tilde{G} is $CI(\tilde{G})=0.96006 > \theta = 0.9$, so the aggregated NFPR \tilde{G} is acceptably consistent.

According to the Definition 3.4, $S(\tilde{g}_i) = \sum_{j=1}^n S(\tilde{g}_{ij})$ is calculated to rank the cities. We first obtained the individual values $S(\tilde{g}_1) = -0.1855$, $S(\tilde{g}_2) = -0.0924$, $S(\tilde{g}_3) = 0.2124$, $S(\tilde{g}_4) = 0.0655$ followed by $S(\tilde{g}_3) > S(\tilde{g}_4) > S(\tilde{g}_2) > S(\tilde{g}_1)$, therefore the ranking of four cities is $x_3 \succ x_4 \succ x_2 \succ x_1$.

In order to analyze the parameter β , we computed the results of ranking as listed in Table 4 and Fig. 4:

INSERT TABLE 4 AND FIGURE 4 HERE

The rankings based on the $\tilde{A}_z(\lambda)$ with $z \in \{1,2,3,4\}$, which indicate the original preference of four DMs (tourists), are stated as follows.

INSERT TABLE 5 AND FIGURES (5, 6) HERE.

6.4. Discussions

In this section, we discuss the proposed MCGDM-NFPRs in comparison with the other two methods, according to Tables (1-5) and Figs. (1-6) and based on Cases (1, 2). The findings are discussed in the following six parts.

(a) As shown in Table 1 and Fig. 1, the results of the best destination are the same in our proposed approach and rough AHP-MABAC. It is also clear from Fig.1 that the tendencies of ranking of the two methods are similar thus validating our proposed method, especially the usefulness of the proposed MAD based aggregation approach.

(b) Table 2 shows that the ranking of cities (alternatives) Hyderabad (A_4) and Kochi (A_9) are

different in two methods of Case 1. In order to find out the reason, we displayed the ranking in our method using the un-normalized original data in Fig. 1 and observe that the rankings of A_4 and A_9 in the un-normalized data were closer to the ranking of rough AHP-MABAC compared to the normalized data. However, since the normalized data is logically consistent, it helps avoid inconsistent information during the decision making. Therefore our proposed method could help deduce any information inconsistency or distortion in the given information.

(c) The preference values of one alternative over another would be fixed no matter how the other alternatives change, so our method would not change the best alternative when a non-optimal alternative is replaced by another worse alternative, further proving the stability of MCGDM-NFPRs.

(d) From Table 4 and Fig. 4, we can see that the ranking of x_i changes with β . Since the weights of $\tilde{A}_1(\lambda)$ and $\tilde{A}_3(\lambda)$ are always higher than those of $\tilde{A}_2(\lambda)$ and $\tilde{A}_4(\lambda)$, respectively, there must exist $x_4, x_3 \succ x_1, x_2$. When $0 \leq \beta \leq 0.5$, the differences between the weights of w_1, w_2 and w_3, w_4 are significant, so $x_4 \succ x_3$; $x_3 \succ x_4$ while $\beta \geq 0.5$. On the other hand, when $\beta \leq 0.8$, the weight w_1 is significant so that $x_1 \succ x_2$, and $x_2 \succ x_1$ when $\beta > 0.8$. We can then draw the conclusion that if the DMs wish to differentiate the experts' judgments and not to make the difference too big, a greater value of β will be more appropriate.

(e) According to Table 5 and Figs. (5, 6), the original rankings of the four alternatives (enterprises) are different for the four experts (executives), which implies that the preferences of four experts differ from others which is a common phenomenon and a crucial problem in the process of GDM. Our algorithm could deal with this issue with NFPRs that are more flexible and applicable than the IPPRs since they help DMs express their preferences comprehensively and in

more detail. Furthermore, the ranking in the result of the example where $\beta=1$ is the same as that of Wang et al. [29], which indicates the feasibility of our proposed method.

(f) In Case 2, the results of proposed method and Wang et al. [29] are the same but this paper uses NFPRs instead of the IPRs in [29] and therefore could express more information. In addition, we can set the indeterminacy-membership function of an SVN to zero instead of an IFS making our method is more flexible.

7. Conclusion

In the present scenario, the medical tourism industry is booming around the world, due to the economic prosperity, cultural development and frequent exchanges between countries. However, a vital problem for a patient-tourist is to choose the ideal city based on the infrastructure, services, and policies. This paper proposes the MCGDM-NFPRs model and applies it to the evaluation and selection of the optimum medical tourism destinations. The MCGDM-NFPRs model under neutrosophic environment is mainly composed by four aspects: (1). the measurements of additive consistency and acceptable consistency for NFPRs, (2). the approach to improve the consistency for unacceptably consistent NFPRs; (3). the aggregation method for NFPRs, and (4) the way to rank the alternatives represented by the NFPRs.

Two illustrative examples were put up to verify the practicability and validity of the proposed approach by comparing it with other two methods. The results clearly indicate that the proposed approach is a valid, stable and convenient tool to evaluate and prioritize healthcare tourism destinations.

Further work is necessary to solve the original incomplete data describing the preference values among alternatives (cities), the main obstacles are how to fill up the missing data according to the

logic of experts and the universality of SVNEs, and how to compute the consistency index of incomplete NFPR accurately. Another topic that needs to be considered is how to recommend different destinations for different people i.e. personalized or 'tailor-made' recommendations.

Appendix A. Proof of Theorem 3.1.

If $S(\tilde{a})$ be the score function of the SVNE \tilde{a} , then $S(\tilde{a}) = (T_a(x) - F_a(x))(1 - I_a(x))$, as per Definition 2.2, we can get that $-1 \leq T_a(x) - F_a(x) \leq 1$ and $0 \leq 1 - I_a(x) \leq 1$, so the conclusions $-1 \leq S'(\tilde{a}) \leq 1$ and $-1 \leq S(\tilde{a}) \leq 1$ are proved; Similarly, the conclusion $0 \leq H'(\tilde{a}) \leq 1$ can be proved based on the Definition 2.2.

Appendix B. Proof of Theorem 3.2.

Let $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ be an additive NFPR, then according to Eq. (6), we have

$$T_{ij}(1 - I_{ij}) + T_{jk}(1 - I_{jk}) + T_{ki}(1 - I_{ki}) = T_{kj}(1 - I_{kj}) + T_{ji}(1 - I_{ji}) + T_{ik}(1 - I_{ik}) \text{ for any } i, j, k \in \{1, 2, \dots, n\}.$$

Then we can get $T_{ij}(1 - I_{ij}) - F_{ij}(1 - I_{ij}) = T_{ik}(1 - I_{ik}) - F_{ik}(1 - I_{ik}) - (T_{jk}(1 - I_{jk}) - F_{jk}(1 - I_{jk}))$ based on Eq

(5), so $(T_{ij} - F_{ij})(1 - I_{ij}) = (T_{ik} - F_{ik})(1 - I_{ik}) - (T_{jk} - F_{jk})(1 - I_{jk})$, Therefore, we can obtain that

$S(\tilde{a}_{ij}) = S(\tilde{a}_{ik}) - S(\tilde{a}_{jk})$. On the other hand, if $S(\tilde{a}_{ij}) = S(\tilde{a}_{ik}) - S(\tilde{a}_{jk})$ for any $i, j, k \in \{1, 2, \dots, n\}$, then

$T_{ij}(1 - I_{ij}) + T_{jk}(1 - I_{jk}) + T_{ki}(1 - I_{ki}) = T_{kj}(1 - I_{kj}) + T_{ji}(1 - I_{ji}) + T_{ik}(1 - I_{ik})$ for any $i, j, k \in \{1, 2, \dots, n\}$, so the

NFPR $\tilde{A} = (\tilde{a}_{ij})_{n \times n}$ is additive consistent.

Appendix C. Proof of Theorem 3.3.

(1) Because $|T_{aij}(1 - I_{aij}) - T_{bij}(1 - I_{bij})| \geq 0$ and $|F_{aij}(1 - I_{aij}) - F_{bij}(1 - I_{bij})| \geq 0$, one can get $MAD(\tilde{A}, \tilde{B}) \geq 0$;

As per Definition 2.2, $T_{aij}(1-I_{aij})$, $T_{bij}(1-I_{bij})$, $F_{aij}(1-I_{aij})$, $F_{bij}(1-I_{bij})$ are all belong to the interval $[0,1]$ for any $i, j \in \{1,2,\dots,n\}$, then $-1 \leq T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij}) \leq 1$ and $-1 \leq F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij}) \leq 1$. It is formed that $|T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})| \leq 1$ and $|F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij})| \leq 1$, so $|T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})| + |F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij})| \leq 2$, as per Eq. (13), $MAD(\tilde{A}, \tilde{B}) \leq 1$ is proved.

(2) As per Eq. (13), since $|T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})| = |T_{bij}(1-I_{bij}) - T_{aij}(1-I_{aij})|$ and $|F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij})| = |F_{bij}(1-I_{bij}) - F_{aij}(1-I_{aij})|$, $MAD(\tilde{A}, \tilde{B}) = MAD(\tilde{B}, \tilde{A})$ is proved.

(3) As $F_{aij} = T_{aji}$ in \tilde{A} and $F_{bij} = T_{bji}$ in \tilde{B} , one can obtain that $|F_{aij}(1-I_{aij}) - F_{bij}(1-I_{bij})| = |T_{aji}(1-I_{aji}) - T_{bji}(1-I_{bji})|$, since $i, j \in \{1,2,\dots,n\}$, then $|T_{aji}(1-I_{aji}) - T_{bji}(1-I_{bji})| = |T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})|$, so we can get the conclusion that

$$MAD(\tilde{A}, \tilde{B}) = \frac{1}{n(n-1)} \sum_{i=1}^n \sum_{j=1, j \neq i}^n |T_{aij}(1-I_{aij}) - T_{bij}(1-I_{bij})|.$$

Appendix D. Proof of Definition 4.1.

The NFPR $\hat{A} = (\hat{a}_{ij})_{n \times n}$ is additive consistent because it satisfies the following properties.

- (a) $0 \leq \hat{T}_{ij}, \hat{I}_{ij}, \hat{F}_{ij} \leq 1$, for any $i, j \in \{1,2,\dots,n\}$;
- (b) $\hat{T}_{ii} = \hat{F}_{ii} = 0.5$ and $\hat{I}_{ii} = 0$, for any $i, j \in \{1,2,\dots,n\}$;
- (c) $\hat{T}_{ij} = \hat{F}_{ji}$, $\hat{F}_{ij} = \hat{T}_{ji}$, for any $i, j \in \{1,2,\dots,n\}$;
- (d) $\hat{T}_{ij}(1-\hat{I}_{ij}) + \hat{T}_{jk}(1-\hat{I}_{jk}) + \hat{T}_{ki}(1-\hat{I}_{ki}) = \hat{T}_{kj}(1-\hat{I}_{kj}) + \hat{T}_{ji}(1-\hat{I}_{ji}) + \hat{T}_{ik}(1-\hat{I}_{ik})$, for any $i, j \in \{1,2,\dots,n\}$.

The properties (a), (b) and (c) can be easily obtained from Eq. (5) and Eq. (15). As per Eq. (15), we can get

$$\begin{aligned} \hat{T}_{ij}(1-\hat{I}_{ij}) + \hat{T}_{jk}(1-\hat{I}_{jk}) + \hat{T}_{ki}(1-\hat{I}_{ki}) &= 0.5(T_{ij}I_{ij} + T_{ji}I_{ji}) + 0.5(T_{jk}I_{jk} + T_{kj}I_{kj}) + 0.5(T_{ki}I_{ki} + T_{ik}I_{ik}) \\ &= 0.5(T_{kj}I_{kj} + T_{jk}I_{jk}) + 0.5(T_{ji}I_{ji} + T_{ij}I_{ij}) + 0.5(T_{ik}I_{ik} + T_{ki}I_{ki}) \\ &= \hat{T}_{kj}(1-\hat{I}_{kj}) + \hat{T}_{ji}(1-\hat{I}_{ji}) + \hat{T}_{ik}(1-\hat{I}_{ik}) \end{aligned}$$

So the property (d) is also proved. Then the proof is completed.

Appendix E. Proof of Theorem 4.1.

Similar to the Proof of Definition 4.1, the Theorem 4.1 can be proved as follows.

- (a) $0 \leq \tilde{T}_{ij}', \tilde{I}_{ij}', \tilde{F}_{ij}' \leq 1$, for any $i, j \in \{1, 2, \dots, n\}$;
- (b) $\tilde{T}_{ii}' = \tilde{F}_{ii}' = 0.5$ and $\hat{I}_{ii} = 0$, for any $i, j \in \{1, 2, \dots, n\}$;
- (c) $\tilde{T}_{ij}' = \tilde{F}_{ji}'$, $\tilde{F}_{ij}' = \tilde{T}_{ji}'$, for any $i, j \in \{1, 2, \dots, n\}$;
- (d) $\tilde{T}_{ij}'(1 - \tilde{I}_{ij}') + \tilde{T}_{jk}'(1 - \tilde{I}_{jk}') + \tilde{T}_{ki}'(1 - \tilde{I}_{ki}') = \tilde{T}_{kj}'(1 - \tilde{I}_{kj}') + \tilde{T}_{ji}'(1 - \tilde{I}_{ji}') + \tilde{T}_{ik}'(1 - \tilde{I}_{ik}')$, for any $i, j \in \{1, 2, \dots, n\}$.

The proofs of (a)-(c) are easily to obtain based on Eq. (5) and Eq. (16). As per Eq. (16), one can get

$$\begin{aligned} \tilde{T}_{ij}'(1 - \tilde{I}_{ij}') + \tilde{T}_{jk}'(1 - \tilde{I}_{jk}') + \tilde{T}_{ki}'(1 - \tilde{I}_{ki}') &= \frac{\hat{T}_{ij}(1 - \hat{I}_{ij}) + t}{1 + 2t} + \frac{\hat{T}_{jk}(1 - \hat{I}_{jk}) + t}{1 + 2t} + \frac{\hat{T}_{ki}(1 - \hat{I}_{ki}) + t}{1 + 2t} \\ &= \frac{\hat{T}_{ij}(1 - \hat{I}_{ij}) + \hat{T}_{jk}(1 - \hat{I}_{jk}) + \hat{T}_{ki}(1 - \hat{I}_{ki}) + 3t}{1 + 2t} \\ \tilde{T}_{kj}'(1 - \tilde{I}_{kj}') + \tilde{T}_{ji}'(1 - \tilde{I}_{ji}') + \tilde{T}_{ik}'(1 - \tilde{I}_{ik}') &= \frac{\hat{T}_{kj}(1 - \hat{I}_{kj}) + t}{1 + 2t} + \frac{\hat{T}_{ji}(1 - \hat{I}_{ji}) + t}{1 + 2t} + \frac{\hat{T}_{ik}(1 - \hat{I}_{ik}) + t}{1 + 2t} \\ &= \frac{\hat{T}_{kj}(1 - \hat{I}_{kj}) + \hat{T}_{ji}(1 - \hat{I}_{ji}) + \hat{T}_{ik}(1 - \hat{I}_{ik}) + 3t}{1 + 2t} \end{aligned}$$

According to Eq. (15), the proof (d) is proved and the proof of the Theorem 4.1 is completed.

Appendix F. Proof of Theorem 4.2.

Let $\hat{a}_{ij} = \langle \hat{T}_{ij}, \hat{I}_{ij}, \hat{F}_{ij} \rangle$, then

$$\begin{aligned} \sum_{l=1}^n (T_{il}(1 - I_{il}) - T_{jl}(1 - I_{jl})) - \sum_{l=1}^n (T_{li}(1 - I_{li}) - T_{lj}(1 - I_{lj})) &= \sum_{l=1}^n (T_{il}(1 - I_{il}) + T_{ij}(1 - I_{ij}) - T_{jl}(1 - I_{jl}) - T_{li}(1 - I_{li})) \\ &= \sum_{l=1}^n (T_{ij}(1 - I_{ij}) - T_{ji}(1 - I_{ji})) = n(T_{ij}(1 - I_{ij}) - T_{ji}(1 - I_{ji})) \end{aligned}$$

As per the Definition 4.1, $\hat{T}_{ij}(1 - \hat{I}_{ij}) = 0.5(T_{ij}(1 - I_{ij}) - T_{ji}(1 - I_{ji})) + 0.5(T_{ij}(1 - I_{ij}) + T_{ji}(1 - I_{ji}))$, then

$$\hat{T}_{ij}(1 - \hat{I}_{ij}) = T_{ij}(1 - I_{ij}), \text{ thus } \tilde{A} = \tilde{A}'.$$

Appendix G. Proof of Theorem 4.3.

As for the Definition 4.2 and Eq. (17), one can easily obtain that $T_{ij}(\lambda) = F_{ji}(\lambda)$, $F_{ij}(\lambda) = T_{ji}(\lambda)$,

$I_{ij}(\lambda) = I_{ji}(\lambda)$, $T_{ii}(\lambda) = F_{ii}(\lambda) = 0.5$ and $I_{ii}(\lambda) = 0$ for any $i, j \in \{1, 2, \dots, n\}$, and the proof is completed.

Appendix H. Proof of Theorem 4.4.

According to Eq. (10), one can obtain $CI(\tilde{A}) = 1 - \frac{1}{3n(n-1)(n-2)} \dot{T}(\tilde{A})$, where

$$\dot{T}(\tilde{A}) = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n |T_{ij}(1-I_{ij}) + T_{jk}(1-I_{jk}) + T_{ki}(1-I_{ki}) - T_{ji}(1-I_{ji}) - T_{kj}(1-I_{kj}) - T_{ik}(1-I_{ik})|. \text{ Similarly, we}$$

can get $CI(\tilde{A}(\lambda)) = 1 - \frac{1}{3n(n-1)(n-2)} \dot{T}(\tilde{A}(\lambda))$ where

$$\dot{T}(\tilde{A}(\lambda)) = \sum_{i=1}^n \sum_{j=1, j \neq i}^n \sum_{k=1, k \neq i, j}^n \left| \begin{array}{l} T_{ij}(\lambda)(1-I_{ij}(\lambda)) + T_{jk}(\lambda)(1-I_{jk}(\lambda)) + T_{ki}(\lambda)(1-I_{ki}(\lambda)) \\ - T_{ji}(\lambda)(1-I_{ji}(\lambda)) - T_{kj}(\lambda)(1-I_{kj}(\lambda)) - T_{ik}(\lambda)(1-I_{ik}(\lambda)) \end{array} \right|, \text{ which means that}$$

$CI(\tilde{A}(\lambda)) = 1 - \frac{1-\lambda}{3n(n-1)(n-2)} \dot{T}(\tilde{A})$, then $CI(\tilde{R}(\lambda)) = CI(\tilde{R}) + \lambda(1 - CI(\tilde{R}))$. Therefore, $CI(\tilde{A}(\lambda)) \geq \theta$ if

$$\frac{\theta - CI(\tilde{A})}{1 - CI(\tilde{A})} \leq \lambda \leq 1, \text{ thus the proof of Theorem 4.4 is completed.}$$

Yan Yang is a PhD degree candidate in Management Science and Engineering at School of Business, Central South University, China. Her primary research interests lie in decision-making theory and its application in medical big data analysis.

Junhua Hu is a professor in School of Business at the Central South University, Changsha, China. He received his PhD degree in Management Engineering from Chiba Institute of Technology, Chiba-ken, Japan. His research interests are in the areas of medical big data analysis, decision-making theory and method, e-commerce, logistics and supply chain management, financial risk management.

Ruixiao Sun is an M.S. degree candidate in Management Science and Engineering at the School of Business, Central South University, China. Her current research interests include decision-making theory and its application in medical decision, recommendation system, etc.

Xiaohong Chen is a professor in School of Business at the Central South University, Changsha, China. She holds her PhD degree from Tokyo Institute of Technology, Tokyo, Japan. Her research interests cover decision theory and decision support system, SMEs financing and management, two-oriented society, etc.
