

you get magnets spinning in a magnets chamber through electricity and the kinetic energy produced is transformed into heat and the magnets are dipped inside water that evaporates and makes more electricity and some magnets tied to the spaceship and others let to fly through propelling them with air maybe even propelling all the magnets through other heat chambers you get chambers that are huge enough to let the water cooldown and then the water streams back to the magnet heat water bank and before that electricity is maintained through dripping water but you need large spaceships to carry the heat you could build colonies on the heat tanks you could put ice too inside the spaceship and make the tank parts of the spaceship out of thermos
