

Quick Disproof of the Riemann Hypothesis

Jonathan W. Tooker

June 5, 2020

Abstract

In this brief note, we propose a set of operations for the affinely extended real number called infinity. Under the terms of the proposition, we show that the Riemann zeta function has infinitely many non-trivial zeros on the complex plane and off the critical line.

§1 Definitions

Definition 1.1 The number infinity, which like the imaginary number is not a real number, is defined as

$$\lim_{x \rightarrow 0^\pm} \frac{1}{x} = \pm\infty .$$

Definition 1.2 The real number line is a 1D space extending infinitely far in both directions. It is represented in set and interval notations respectively as

$$\mathbb{R} = \{x \mid -\infty < x < \infty\} , \quad \text{and} \quad \mathbb{R} \equiv (-\infty, \infty) .$$

Definition 1.3 A number x is a real number if and only if it is a cut in the real number line

$$(-\infty, \infty) = (-\infty, x) \cup [x, \infty) .$$

Definition 1.4 The affinely extended real numbers are constructed as $\overline{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$. They are represented in set and interval notations respectively as

$$\overline{\mathbb{R}} = \{x \mid -\infty \leq x \leq \infty\} , \quad \text{and} \quad \overline{\mathbb{R}} \equiv [-\infty, \infty] .$$

$\overline{\mathbb{R}}$ is called the affinely extended real number line.

Definition 1.5 A number x is an affinely extended real number $x \in \overline{\mathbb{R}}$ if and only if $x = \pm\infty$ or it is a cut in the affinely extended real number line

$$[-\infty, \infty] = [-\infty, x) \cup [x, \infty] .$$

Theorem 1.6 *If $x \in \overline{\mathbb{R}}$ and $x \neq \pm\infty$, then $x \in \mathbb{R}$.*

Proof. Proof follows from Definition 1.4. ☞

Definition 1.7 Infinity has the properties of additive and multiplicative absorption:

$$x \in \mathbb{R} \ , \ x > 0 \quad \Longrightarrow \quad \begin{cases} \pm x + \infty = \infty \\ \pm x \times \infty = \pm\infty \end{cases} .$$

Proposition 1.8 Suppose the additive absorptive property of $\pm\infty$ is taken away when it appears as $\pm\widehat{\infty}$. Further suppose that $\|\widehat{\infty}\| = \infty$ and that the ordering is such that

$$\begin{aligned} n &< \widehat{\infty} - b < \widehat{\infty} - a < \infty \\ -\infty &< -\widehat{\infty} + a < -\widehat{\infty} + b < -n \ , \end{aligned}$$

for any positive $a, b \in \mathbb{R}$, $a < b < n$, and any natural number $n \in \mathbb{N}$.

Theorem 1.9 $\widehat{\infty}$ is

$$\pm\widehat{\infty} = \lim_{x \rightarrow 0^\pm} \frac{1}{x} .$$

Proof. Proof follows from the $\|\widehat{\infty}\| = \infty$ condition given in Proposition 1.8. ☞

Theorem 1.10 *If $x = \pm(\widehat{\infty} - b)$ and $0 < b < n$ for some $n \in \mathbb{N}$, then $x \in \mathbb{R}$.*

Proof. By the ordering given in Proposition 1.8, we have

$$[\infty, \infty] = [-\infty, x] \cup [x, \infty] .$$

It follows from Definition 1.5 that $x \in \overline{\mathbb{R}}$. Since $\widehat{\infty}$ does not have additive absorption and the theorem states that $b > 0$, it follows from the ordering that

$$x \neq \pm\widehat{\infty} \ , \quad \text{and} \quad x \neq \pm\infty .$$

It follows from Theorem 1.6 that $x \in \mathbb{R}$. ☞

Theorem 1.11 *If a, b are positive numbers less than some natural number $n \in \mathbb{N}$, then*

$$(\widehat{\infty} - a) - (\widehat{\infty} - b) = b - a .$$

Proof. Observe that

$$(\widehat{\infty} - a) - (\widehat{\infty} - b) = \lim_{x \rightarrow 0} \left(\frac{1}{x} - a - \frac{1}{x} + b \right) = b - a . \quad \text{☞}$$

Theorem 1.12 *If $a, b \in \mathbb{R}$ are positive numbers less than some natural number $n \in \mathbb{N}$, then the quotient $(\widehat{\infty} - b)/(\widehat{\infty} - a)$ is identically one.*

Proof. Observe that

$$\frac{\widehat{\infty} - b}{\widehat{\infty} - a} = \lim_{x \rightarrow 0} \left(\frac{\frac{1}{x} - b}{\frac{1}{x} - a} \right) = \lim_{x \rightarrow 0} \left(\frac{\frac{1}{x} - b}{\frac{1}{x} - a} \cdot \frac{x}{x} \right) = \lim_{x \rightarrow 0} \frac{1 - bx}{1 - ax} = 1 \quad \cdot \quad \text{☞}$$

Definition 1.13 A number is a complex number $z \in \mathbb{C}$ if and only if

$$z = x + iy \quad , \quad \text{and} \quad x, y \in \mathbb{R} \quad .$$

§2 Disproof of the Riemann Hypothesis

Theorem 2.1 *If $b, y_0 \in \mathbb{R}$, if $0 < b < n$ for some $n \in \mathbb{N}$, if $z_0 = (\widehat{\infty} - b) + iy_0$, and if $\zeta(z)$ is the Riemann ζ function, then $\zeta(z_0) = 1$.*

Proof. Observe that the Dirichlet sum form of ζ [1] takes z_0 as

$$\begin{aligned} \zeta(z_0) &= \sum_{n=1}^{\infty} \frac{1}{n^{(\widehat{\infty}-b)+iy_0}} \\ &= \sum_{n=1}^{\infty} \frac{n^b}{n^{\widehat{\infty}}} \left(\cos(y_0 \ln n) - i \sin(y_0 \ln n) \right) \\ &= 1 + \sum_{n=2}^{\infty} 0 \left(\cos(y_0 \ln n) - i \sin(y_0 \ln n) \right) = 1 \quad . \quad \text{☞} \end{aligned}$$

Theorem 2.2 *The Riemann ζ function has non-trivial zeros at certain $z \in \mathbb{C}$ outside of the critical strip.*

Proof. Riemann's functional form of ζ [1] is

$$\zeta(z) = \frac{(2\pi)^z}{\pi} \sin\left(\frac{\pi z}{2}\right) \Gamma(1-z)\zeta(1-z) \quad .$$

Theorem 2.1 gives $\zeta(\widehat{\infty} - b)$ when we set $y_0 = 0$ so we will use Riemann's equation to prove this theorem by solving for $z = -(\widehat{\infty} - b) + 1$. (This value for z follows from $1 - z = \widehat{\infty} - b$.) We have

$$\begin{aligned} \zeta[-(\widehat{\infty} - b) + 1] &= \lim_{z \rightarrow -(\widehat{\infty}-b)+1} \left(\frac{(2\pi)^z}{\pi} \sin\left(\frac{\pi z}{2}\right) \right) \lim_{z \rightarrow (\widehat{\infty}-b)} \left(\Gamma(z)\zeta(z) \right) \\ &= \lim_{z \rightarrow -(\widehat{\infty}-b)+1} \left(2 \sin(\pi z/2) \right) \lim_{z \rightarrow (\widehat{\infty}-b)} \left((2\pi)^{-z} \Gamma(z)\zeta(z) \right) \quad . \end{aligned}$$

For the limit involving Γ , we will compute the limit as a product of two limits. We separate terms as

$$\lim_{z \rightarrow (\widehat{\infty} - b)} \left((2\pi)^{-z} \Gamma(z) \zeta(z) \right) = \lim_{z \rightarrow (\widehat{\infty} - b)} \left((2\pi)^{-z} \Gamma(z) \right) \lim_{z \rightarrow (\widehat{\infty} - b)} \zeta(z) .$$

From Theorem 2.1, we know the limit involving ζ is equal to one. For the remaining limit, we will insert the identity and again compute it as the product of two limits. If z approaches $(\widehat{\infty} - b)$ along the real axis, it follows from Theorem 1.12 that

$$1 = \frac{z - (\widehat{\infty} - b)}{z - (\widehat{\infty} - b)} .$$

Inserting the identity yields

$$\lim_{z \rightarrow (\widehat{\infty} - b)} \left((2\pi)^{-z} \Gamma(z) \right) = \lim_{z \rightarrow (\widehat{\infty} - b)} \left((2\pi)^{-z} \Gamma(z) \frac{z - (\widehat{\infty} - b)}{z - (\widehat{\infty} - b)} \right) .$$

Let

$$A = \Gamma(z) \left(z - (\widehat{\infty} - b) \right) , \quad \text{and} \quad B = \frac{(2\pi)^{-z}}{z - (\widehat{\infty} - b)} .$$

To get the limit of A into workable form we will use the property $\Gamma(z) = z^{-1} \Gamma(z + 1)$ to derive an expression for $\Gamma[z - (\widehat{\infty} - b) + 1]$. If we can write $\Gamma(z)$ in terms of $\Gamma[z - (\widehat{\infty} - b) + 1]$, then the limit as z approaches $(\widehat{\infty} - b)$ will be very easy to compute. Observe that

$$\Gamma[z - (\widehat{\infty} - b) + 1] = \Gamma[z - (\widehat{\infty} - b) + 2] \left(z - (\widehat{\infty} - b) + 1 \right)^{-1} .$$

By recursion we obtain

$$\Gamma[z - (\widehat{\infty} - b) + 1] = \Gamma(z) \lim_{n \rightarrow (\widehat{\infty} - b)} \prod_{k=1}^n \left(z - (\widehat{\infty} - b) + k \right)^{-1} .$$

Rearrangement yields

$$\Gamma(z) = \Gamma[z - (\widehat{\infty} - b) + 1] \lim_{n \rightarrow (\widehat{\infty} - b)} \prod_{k=1}^n \left(z - (\widehat{\infty} - b) + k \right) .$$

It follows that

$$A = \Gamma[z - (\widehat{\infty} - b) + 1] \lim_{n \rightarrow (\widehat{\infty} - b)} \prod_{k=0}^n \left(z - (\widehat{\infty} - b) + k \right) .$$

The limit of A is

$$\lim_{z \rightarrow (\widehat{\infty} - b)} A = \Gamma[(\widehat{\infty} - b) - (\widehat{\infty} - b) + 1] \lim_{n \rightarrow (\widehat{\infty} - b)} \prod_{k=0}^n \left((\widehat{\infty} - b) - (\widehat{\infty} - b) + k \right) .$$

Theorem 1.11 gives $(\widehat{\infty} - b) - (\widehat{\infty} - b) = 0$ so

$$\lim_{z \rightarrow (\widehat{\infty} - b)} A = \Gamma(1) \lim_{n \rightarrow (\widehat{\infty} - b)} \prod_{k=0}^n k = 0 \ .$$

Direct evaluation of the limit of B gives $0/0$ so we need to use L'Hôpital's rule which gives

$$\begin{aligned} \lim_{z \rightarrow (\widehat{\infty} - b)} B &\stackrel{*}{=} \lim_{z \rightarrow (\widehat{\infty} - b)} \left(\frac{\frac{d}{dz}(2\pi)^{-z}}{\frac{d}{dz}(z - (\widehat{\infty} - b))} \right) \\ &= \lim_{z \rightarrow (\widehat{\infty} - b)} \frac{d}{dz} e^{-z \ln(2\pi)} \\ &= -\ln(2\pi) e^{-(\widehat{\infty} - b) \ln(2\pi)} = \frac{-1}{e^{\widehat{\infty}}} \ln(2\pi) e^{b \ln(2\pi)} = 0 \end{aligned}$$

Therefore, we find that the limit of AB is 0. It follows that

$$\zeta[-(\widehat{\infty} - b) + 1] = \lim_{z \rightarrow -(\widehat{\infty} - b) + 1} 2 \sin\left(\frac{\pi z}{2}\right) \times 0 = 0 \ . \quad \text{☞}$$

Definition 2.3 The Riemann hypothesis as defined by the Clay Mathematics Institute [2] is

The non-trivial zeros of the Riemann ζ function have real parts equal to one half.

Definition 2.4 According to the Clay Mathematics Institute [2], the trivial zeros of ζ are the even negative integers.

Remark 2.5 The zeros demonstrated in Theorem 2.2 are neither on the critical line $\text{Re}(z) = 1/2$ nor are they the negative even integers. Theorem 2.2, therefore, is the negation of the Riemann hypothesis.
